

## Mediterranean Forests in Transition (MEDIT): Deliverable No2

### Title: Report on the results of the functional traits meta-analysis

Due to Project Month 6, Date: 30/09/2012

---

#### Introduction

This manuscript summarises the work done during the first 6 months of the Medit Project, dealing in particular with the functional traits database developed and analysed within component C1 (“Literature Review and Metadata Collection”). This report summarises the development and analysis of the functional traits database. An accompanying report (Deliverable No1) summarises the tree-rings dataset development and meta-analysis.

Within Deliverable No2 I have gathered and analysed functional traits data for 50 forest species commonly found in forest along Greece. The aim of this analysis was to a) develop a start-up dataset to identify data-gaps regarding the functional traits of interest, with particular interest to the Mediterranean basin, b) to use this database in conjunction to the functional traits data gathered in Medit component 4 , and to identify potential trait inter-relationships of interest. These data will be used for the initial parameterisation of the GREFOS and the LPJ model.

#### Methods

##### Dataset Development

In total around 300 trait suites have been gathered for 50 woody forest species commonly found in Greece, classified to 20 families and 28 genera. The geographic extent of this dataset is across Europe covering above 50 scientific publications. The functional traits of interest are leaf longevity (LL [months]), leaf thickness (Lth [mm]), leaf mass per area (LMA [ $\text{g m}^{-2}$ ]), leaf nitrogen concentration (N [ $\text{mg g}^{-1}$ ]), leaf phosphorous concentration (P [ $\text{mg g}^{-1}$ ]), leaf net photosynthetic rate at light saturation ( $A_{\text{max}}$  [ $\mu\text{mol m}^{-2} \text{s}^{-1}$ ]), leaf dark respiration ( $R_d$  [ $\mu\text{mol m}^{-2} \text{s}^{-1}$ ]) and wood density (WD [ $\text{g cm}^{-3}$ ]).

##### Statistics

I first estimated the mean value per family and species for the eight functional traits of interest. These values would be used as reference for the fieldwork and lab work envisaged in C4 of the Medit project. In addition these estimates will be used for the initial parameterisation of the small and large scale models envisaged in C2 and C3.

I also explored for trait intercorrelations that could potentially reveal important axis of plant functional strategies and trade-offs, as discussed in the literature. I used a correlation analysis and a standardised major axis regression for this purpose.

Furthermore, I estimated the taxonomic variation, i.e the apportion of variance at the Family, Genus and Species level for the 50 forest species. I used a hierarchical multilevel model for this purpose.

Finally I used a principal components analysis followed by a clustering algorithm to identify potential species groupings as revealed by their functional characters to numerically define functional groups.

## Results

Table 1 summarises the mean value of the eight functional traits of interests for the 50 taxa. The mean family level values of the functional traits of interest are summarised in Figure 1.

**Figure 1: Mean Family level trait values.**

Table 2 summarises the trait intercorrelations with bold values indicating a statistically significant Pearson correlation coefficient. As expected LMA correlates with most leaf traits underlying its central role in the leaf economic spectrum. WD did not show any significant relationship with the rest of the leaf traits.

**Table 2: Species Pearson correlation coefficient between the functional traits of interest. Bold values indicate a statistically significant relationship.**

**Table 1: Species specific mean trait values for the eight functional traits of interest.**

Figure 2 summarises some of the most interesting relationships between the functional traits of interest that could be eventually used in the parameterisation of both the small and large scale vegetation dynamics model. In all cases a standardised major axis regression line was fit. We note that the values used here are the species level means.

**Figure 2: Standardised major axis regression between key functional traits.**

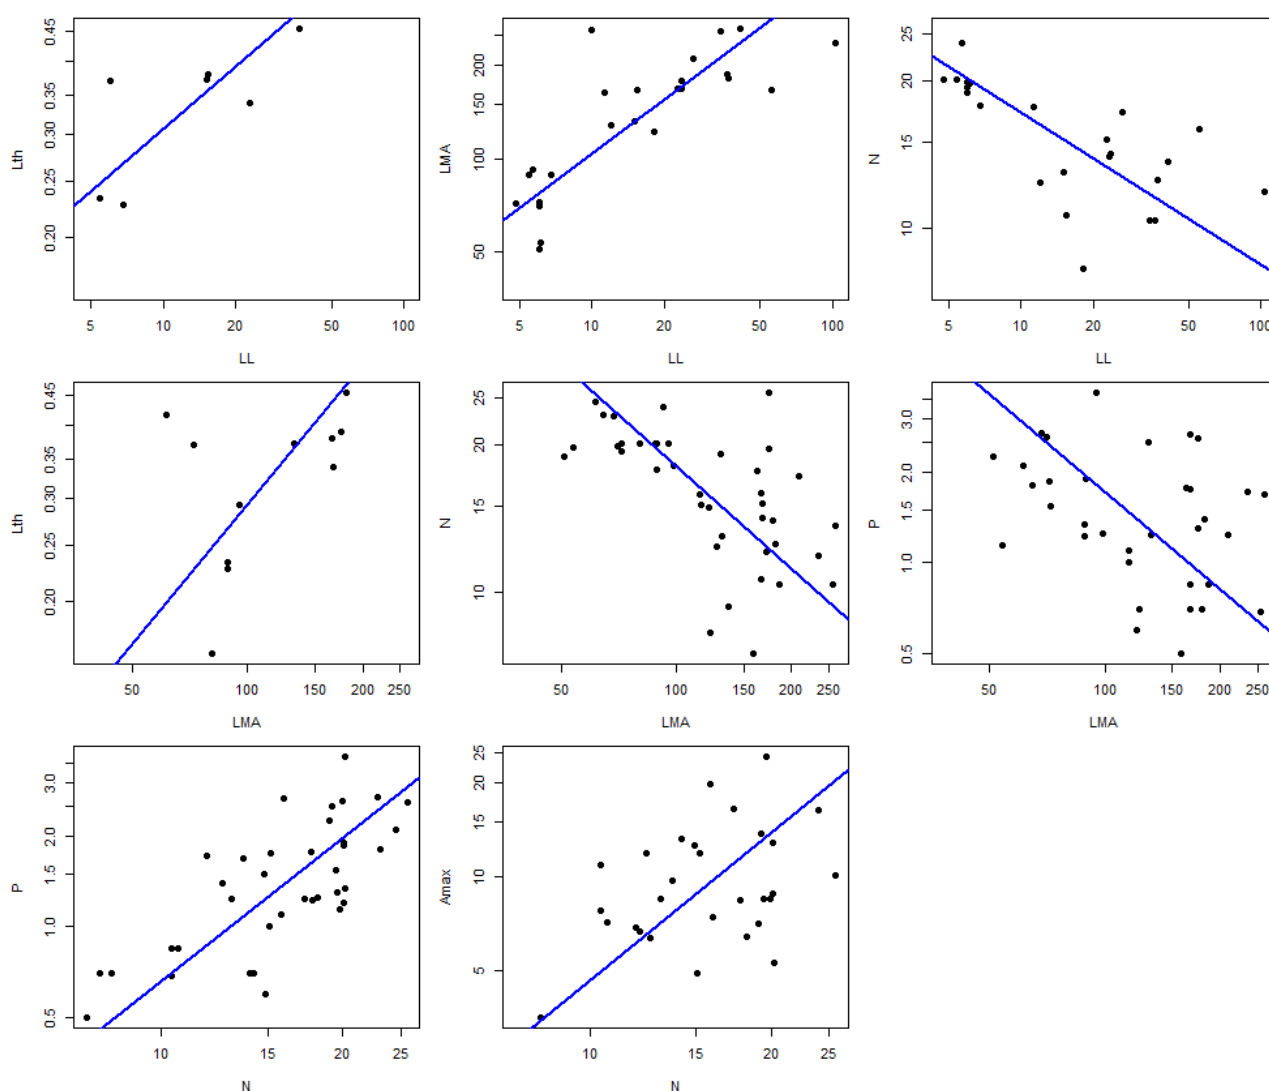

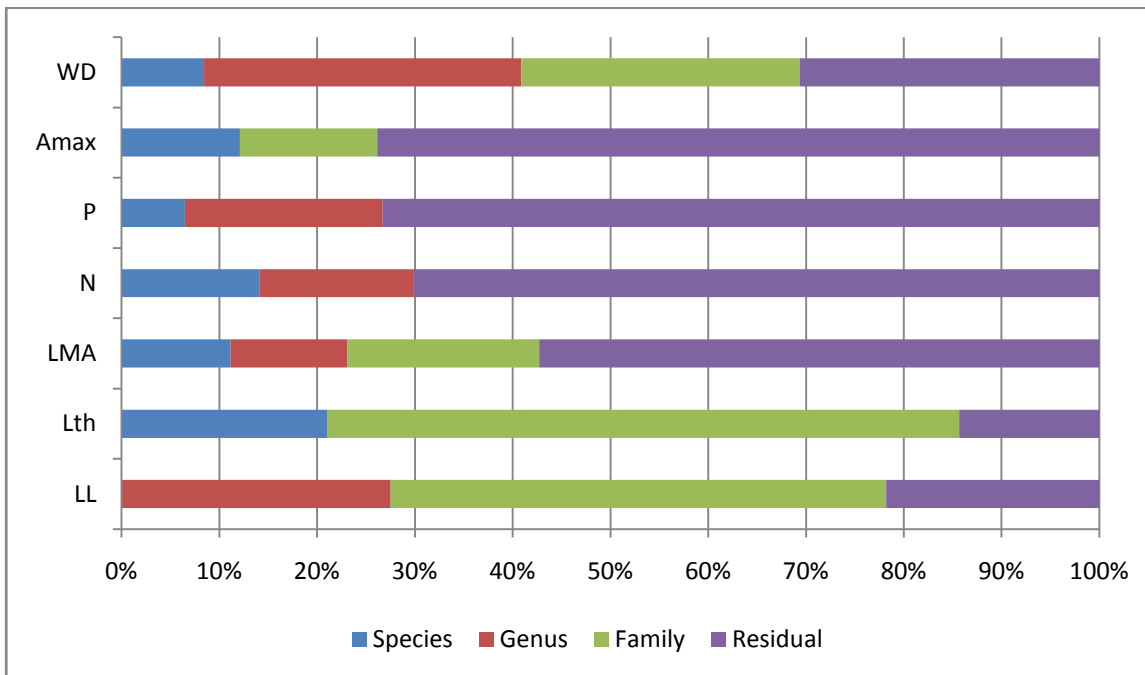

Figure 3 summarises the variance partitioning at the family, genus and species level for seven of the functional traits of interest. We excluded here Rd as there were not enough values recorded in the dataset. For leaf longevity and leaf thickness most of the variation is apportioned at the family level. For LMA, Amax, P and N we note a large portion of the variance being is unexplained suggesting that there could be a strong environmental effect on those traits. WD is a more conservative character with family and genus explaining most of the variation.

**Figure 3: Variance partitioning for seven of the functional traits of interest, using a hierarchical multilevel mode.**

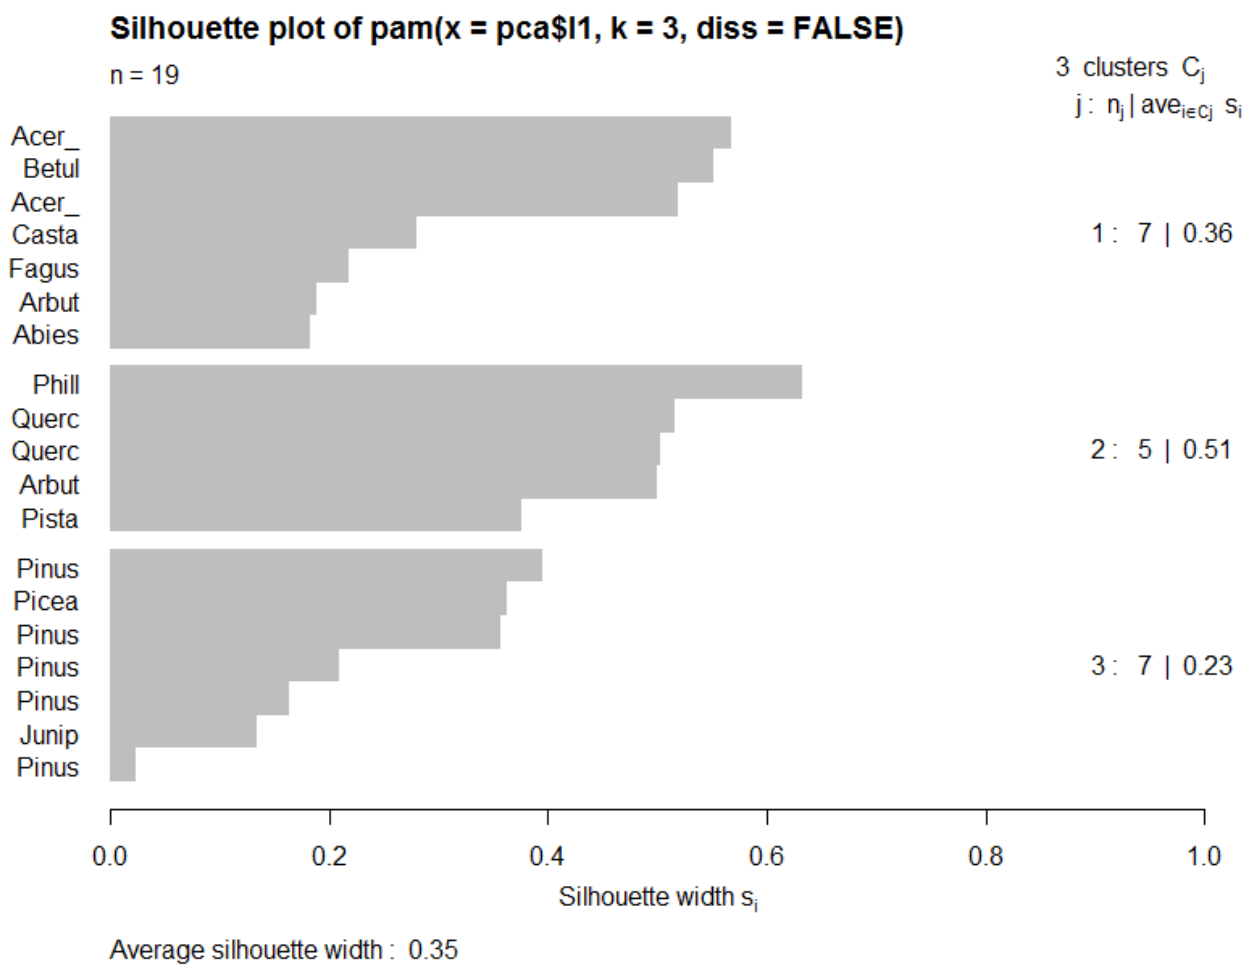

The principal component analysis on the correlation matrix of identified 3 important axes of functional variation in our dataset. A summary of the PCA analysis is presented in table 3. PCA1 represents the leaf economic spectrum with higher N and P concentrations found in smaller LMA leaves.

eigen values	2.09	1.26	1.05
variance explained	0.42	0.25	0.21
	PCA1	PCA2	PCA3
LMA	<b>0.59</b>	<b>-0.59</b>	-0.36
N	<b>-0.96</b>	-0.10	-0.01
P	<b>-0.86</b>	0.03	-0.29
Amax	-0.27	<b>-0.88</b>	-0.12
WD	-0.09	-0.35	<b>0.90</b>

The second PCA axis indicates at higher area based gas exchange rates achieved from leaves with higher LMA. PCA3 seems to point at a growth vs. Tolerance trade off with more active leaves relating with lower wood densities and an overall less tolerant strategy. This analysis will be repeated with the actual MEDIT data gathered and analysed from the fieldwork in C4.

Finally a “clustering around medoids” procedure was implemented to the PCA scores of each species. This clustering identified 3 groups, that could be used a plant functional types in initial parameterisation of the vegetation dynamics models. The three groups nicely classified coniferous, evergreen broadleaves and deciduous broadleaves species, with the only exception of *Abies alba*.

## Conclusions

Analysis of the dataset gathered from the literature identified interesting patterns of functional traits intercorrelations and grouping of species to functional types. This analysis will be further implemented in the MEDIT data, gathered in C4.
